A PIVOTAL METHOD FOR AFFINE VARIATIONAL INEQUALITIES

MENGLIN CAO AND MICHAEL C. FERRIS

ABSTRACT. We explain and justify a path-following algorithm for solving the equations $A_C(x) = a$, where A is a linear transformation from \mathbb{R}^n to \mathbb{R}^n , C is a polyhedral convex subset of \mathbb{R}^n , and A_C is the associated normal map. When A_C is coherently oriented, we are able to prove that the path following method terminates at the unique solution of $A_C(x) = a$, which is a generalization of the well known fact that Lemke's method terminates at the unique solution $\text{LCP}(q, M)$ when M is a \mathbf{P} -matrix. Otherwise, we identify two classes of matrices which are analogues of the class of copositive-plus and L -matrices in the study of the linear complementarity problem. We then prove that our algorithm processes $A_C(x) = a$ when A is the linear transformation associated with such matrices. That is, when applied to such a problem, the algorithm will find a solution unless the problem is infeasible in a well specified sense.

1. INTRODUCTION

In this paper we are concerned with the Affine Variational Inequality problem. The problem can be described as follows. Let C be a polyhedral set and let A be a linear transformation from \mathbb{R}^n to \mathbb{R}^n . We wish to find $z \in C$ such that

$$\langle A(z) - a, y - z \rangle \geq 0, \forall y \in C. \quad (\text{AVI})$$

This problem has appeared in the literature in several disguises. The first is the linear generalized equation, that is

$$0 \in A(z) - a + \partial\psi_C(z), \quad (\text{GE})$$

where $\psi_C(\cdot)$ is the indicator function of the set C defined by

$$\psi_C(z) := \begin{cases} 0 & \text{if } z \in C, \\ \infty & \text{if } z \notin C \end{cases}$$

It can be easily shown that $\partial\psi_C(z) = N_C(z)$, the normal cone to C at z , if $z \in C$ and is empty otherwise, and hence (AVI) is equivalent to (GE). The solutions of such problems arise for example in the determination of a Newton-type method for generalized equations.

The problem has also been termed the linear stationary problem and we refer the reader to the work of [13] for several methods for the solution of this problem either over a bounded polyhedron or a pointed convex polyhedron.

Key words and phrases. Affine variational inequality, normal map, path-following.

This material is based on research supported by the National Science Foundation Grant CCR-9157632 and the Air Force Office of Scientific Research Grant AFOSR-89-0410

In this work we will use the notion of a normal map due to Robinson [11]. The normal map, relating to a function $F: \mathbb{R}^n \rightarrow \mathbb{R}^n$ and a non-empty, closed, convex set C , is defined as

$$F_C(x) := F(\pi_C(x)) + x - \pi_C(x)$$

where $\pi_C(x)$ is the projection (with respect to the Euclidean norm) of x onto the set C . Throughout this paper, we will be concerned with solving affine normal maps, that is, $F \equiv A$ is a linear map, C is a polyhedral set and the solution x satisfies

$$A_C(x) = a \tag{NE}$$

Note that (NE) is equivalent to (AVI), since if $A_C(x) = a$, then $z := \pi_C(x)$ is a solution of (AVI). Furthermore, if z is a solution of (AVI), then $x := z + a - A(z)$ satisfies $A_C(x) = a$. We shall use this equivalence throughout this paper without further reference.

A very familiar special case of (GE) is when $C \equiv K$ is a polyhedral convex cone. Then it is easy to show that (GE) is equivalent to the generalized complementarity problem [7]

$$z \in K, A(z) - a \in K^D, \langle A(z) - a, z \rangle = 0$$

where $K^D := \{z^* \mid \langle z^*, k \rangle \geq 0, \forall k \in K\}$ is the dual cone associated with K . The pivotal technique that we describe here can be thought of as a generalization of the complementary pivot algorithm due to Lemke [8].

In §2 we describe the theoretical algorithm and apply several results of Eaves and Robinson to establish its finite termination for coherently oriented normal maps. In §3 we carefully describe an implementation of such a method, under the assumption that C is given by

$$C := \{z \mid Bz \geq b, Hz = h\}.$$

In §4 we extend several well known results for linear complementarity problems to the affine variational inequality. In particular, we generalize the notions of copositive, copositive-plus and L -matrices from the complementarity literature and prove that our algorithm processes variational inequalities associated with such matrices. That is, when the algorithm is applied to such a problem, either a solution is found, or the problem is infeasible in a well specified sense.

A word about our notation. For any vectors x and y in \mathbb{R}^n , $\langle x, y \rangle$ or $x^T y$ denotes the inner product of x and y , and in this paper, these two notations are freely interchangeable. Each $m \times n$ matrix A represents a linear map from \mathbb{R}^n to \mathbb{R}^m , the symbol A refers to either the matrix or the linear map as determined by the context. Given a linear map A from \mathbb{R}^n to \mathbb{R}^m , for any $X \subset \mathbb{R}^n$, the set $A(X) := \{y \in \mathbb{R}^m \mid y = Ax, \text{ for some } x \in X\}$ is called the image of X under A ; for any set $Y \subset \mathbb{R}^m$, the set $A^{-1}(Y) := \{x \in \mathbb{R}^n \mid Ax \in Y\}$ is referred to as the inverse image of Y under A . In particular, the set $\ker A := A^{-1}(\{0\})$ is called the kernel of A and the set $\text{im } A := A(\mathbb{R}^n)$ is called the image of A . Given a nonempty, closed, convex set C in \mathbb{R}^n , $\text{rec } C := \{d \in \mathbb{R}^n \mid x + \lambda d \in C, \forall x \in C, \forall \lambda \geq 0\}$ is called the recession cone of C and $\text{lin } C = \text{rec } C \cap -\text{rec } C$ is the lineality of C . If F is a function from \mathbb{R}^n to \mathbb{R}^n , then F_C represents the normal map defined above. If C is a polyhedral convex set, a subset G is called a face of C if there exists a vector $c \in \mathbb{R}^n$ such that $G = \arg \max_{x \in C} c^T x$.

2. THEORETICAL ALGORITHM

We describe briefly a theoretical algorithm that is guaranteed to find a solution in finitely many steps when the homeomorphism condition developed in [11] holds. This method is a realization of the general path-following algorithm described and justified in [3]. In what follows we use various terms and concepts that are explained in [3]. Related methods for finding stationary points of affine functions on polyhedral sets are given in [4, 5]. A more detailed description of an implementation of the method is given in the §3; here we deal with theoretical considerations underpinning the method. Other related work can be found in [1].

In order to formulate the algorithm, it is important to understand the underlying geometric structure of the problem. Our approach relies heavily on the normal manifold of the set C , [11], which we will now describe.

Theorem 2.1. *Let C be a nonempty polyhedral convex set in \mathbb{R}^n and let $\{F_i \mid i \in \mathcal{I}\}$ be the nonempty faces of C . For $i \in \mathcal{I}$, define N_{F_i} to be the common value of $N_C(\cdot)$ on $\text{ri } F_i$ and let $\sigma_i := F_i + N_{F_i}$. The normal manifold \mathcal{N}_C of C consists of the pair $(\mathbb{R}^n, \mathcal{S})$, where $\mathcal{S} := \{\sigma_i \mid i \in \mathcal{I}\}$. The faces of the σ_i having dimension $k \geq 0$ are called the k -cells of \mathcal{N}_C . \mathcal{N}_C is a subdivided piecewise linear manifold of dimension n .*

It can be seen that the normal map A_C will agree in each n -cell of this manifold with an affine map, and therefore, with each such cell we can associate the determinant of the corresponding linear transformation. If each of these determinants has the same sign, we say that A_C is coherently oriented. The following is the central result from [11].

Theorem 2.2. *The normal map A_C is a Lipschitzian homeomorphism of \mathbb{R}^n into \mathbb{R}^n if and only if A_C is coherently oriented.*

We will assume first of all that A_C is a homeomorphism of \mathbb{R}^n onto \mathbb{R}^n , so that the same-sign condition holds and describe the algorithm within this framework. Later in the paper, this condition will be weakened. The first step of the algorithm is to determine if C contains any lines. If it does, take orthonormal bases for $\text{lin } C$ and its orthogonal complement according to the scheme explained in [11, Prop. 4.1]. The factoring procedure explained there shows how to reduce the problem to one (which we shall also write $A_C(x) = a$) in a possibly smaller space, in which the set C appearing in this problem contains no lines. In that case, as shown in [11], the determinants associated with A_C in the various cells of \mathcal{N}_C must all have positive sign. Further, C will have an extreme point, say x_e , and as pointed out in [11, §5] the normal cone $N_C(x_e)$ must have an interior. Let e be any element of $\text{int } N_C(x_e)$. An implementation of the factoring procedure is given as stage one of the method described in §3. The construction of an extreme point and element in the interior of the normal cone corresponds to stage two of that method.

Now construct a piecewise-linear manifold \mathcal{M} from \mathcal{N}_C by forming the Cartesian product of each cell of \mathcal{N}_C with \mathbb{R}_+ , the non-negative half-line in \mathbb{R} . This \mathcal{M} will be a PL $(n+1)$ -manifold in \mathbb{R}^{n+1} , as can easily be verified (see [3, Example 4.3]). Define a PL function $F: \mathcal{M} \rightarrow \mathbb{R}^n$ (where \mathbb{R}^n is regarded as a PL manifold of one cell) by:

$$F(x, \mu) = A_C(x) - (\mu e + a).$$

We shall consider solutions $x(\mu)$ of $F(x, \mu) = 0$; it is clear from (NE) that $x(0)$ will solve our problem. Note that since we have assumed A_C to be a homeomorphism, the function

$x(\cdot)$ is single-valued and defined on all of \mathbb{R}_+ , though this property is not essential to our argument.

Now define $w(\mu) = x_e + (a - Ax_e) + \mu e$. It is clear that since

$$w(\mu) = x_e + \mu[e + \mu^{-1}(a - Ax_e)] \quad (1)$$

for large positive μ , $w(\mu)$ lies interior to the cell $x_e + N_C(x_e)$ of \mathcal{N}_C . Therefore $(w(\mu), \mu)$ lies interior to the cell $[x_e + N_C(x_e)] \times \mathbb{R}_+$ of \mathcal{M} , and so it is a regular point of \mathcal{M} . Further, for such μ we have $\pi_C(w(\mu)) = x_e$, so that

$$F(w(\mu), \mu) = Ax_e + (a - Ax_e) + \mu e - (\mu e + a) = 0,$$

and therefore for some $\mu_0 \geq 0$, $F^{-1}(0)$ contains the ray $\{(w(\mu), \mu) \mid \mu \geq \mu_0\}$.

Now we apply the algorithm of [3] to the PL equation $F(x, \mu) = 0$, using a ray start at $(w(\mu_1), \mu_1)$ for some $\mu_1 > \mu_0$ and proceeding in the direction $(-e, -1)$. As the manifold \mathcal{M} is finite, according to [3, Th. 15.13] the algorithm generates, in finitely many steps, either a point (x_*, μ_*) in the boundary of \mathcal{M} with $F(x_*, \mu_*) = 0$, or a ray in $F^{-1}(0)$ different from the starting ray. As the boundary of \mathcal{M} is $\mathcal{N}_C \times \{0\}$, we see that in the first case $\mu_* = 0$ and, by our earlier remarks, x_* then satisfies $A_C(x_*) = a$. Therefore in order to justify the algorithm we need only show that it cannot produce a ray different from the starting ray.

The algorithm in question permits solving the perturbed system $F(x_\epsilon, \mu_\epsilon) = p(\epsilon)$, where $p(\epsilon)$ is of the form

$$p(\epsilon) = \sum_{i=1}^n p_i \epsilon^i$$

for appropriately chosen vectors p_i . It is shown in [3] that $p(\epsilon)$ is a regular value of F for each small positive ϵ , and it then follows by [3, Th. 9.1] that for such ϵ , $F^{-1}(p(\epsilon))$ is a connected 1-manifold $Y(\epsilon)$, whose boundary is equal to its intersection with the boundary of \mathcal{M} , and which is subdivided by the chords formed by its intersections with the cells of \mathcal{M} that it meets. Finally, for an easily computed function

$$b(\epsilon) = \sum_{i=1}^n b_i \epsilon^i$$

we have $(w(\mu_1), \mu_1) + b(\epsilon) \in Y(\epsilon)$, and for small positive ϵ this point evidently lies on a ray in $F^{-1}(p(\epsilon))$. Because we start on this ray, $Y(\epsilon)$ cannot be homeomorphic to a circle, and therefore it is homeomorphic to an interval.

A simple computation at the starting point shows that the curve index [3, §12] at that point is -1 . By [3, Lemma 12.1] this index will be constant along $Y(\epsilon)$. However, a computation similar to that in [3, Lemma 12.3] shows that in each cell of \mathcal{M} , if the direction of $Y(\epsilon)$ in that cell is (r, ρ) then

$$(\text{sgn } \rho)(\text{sgn } \det T) = -1$$

where T is the linear transformation associated with A_C in the corresponding cell of \mathcal{N}_C . Under our hypotheses, $\det T$ must be positive, and therefore ρ is negative everywhere along $Y(\epsilon)$. But this means that the parameter μ decreases strictly in each cell of linearity that $Y(\epsilon)$ enters, and it follows from the structure of \mathcal{M} that after finitely many steps we must have $\mu = 0$, and therefore we have a point x_ϵ with $A_C(x_\epsilon) = a + p(\epsilon)$.

Now in practice the algorithm does not actually use a positive ϵ , but only maintains the information necessary to compute $Y(\epsilon)$ for all small positive ϵ , employing the lexicographic

ordering to resolve possible ambiguities when $\epsilon = 0$. Therefore after finitely many steps it will actually have computed x_0 with $A_C(x_0) = a$.

Note that for linear complementarity problems, the above algorithm corresponds to Lemke's method [8]. It is well known that for linear complementarity problems associated with \mathbf{P} -matrices, Lemke's method terminates at a solution. For variational inequalities, we have a similar result due to the analysis above.

Theorem 2.3. *Given the problem (NE), assume that A_C is coherently oriented; then the path following method given in this section terminates at a solution of (NE).*

3. ALGORITHM IMPLEMENTATION

The previous section described a method for solving the Affine Variational Inequality over a general polyhedral set and showed (under a lexicographical ordering) that a coherently oriented normal equation (NE) can be solved in a finite number of iterations by a path-following method. In this section, we describe the numerical implementation of such a method, giving emphasis to the numerical linear algebra required to perform the steps of the algorithm.

We shall specialize to the case where C is given as

$$C := \{z \mid Bz \geq b, Hz = h\} \quad (2)$$

and we shall assume that the linear transformation $A(z)$ is represented by the matrix A in our current coordinate system. We can describe our method to solve the normal equation in three stages. Note that by "solving", we mean producing a pair $(x, \pi(x))$, where x is a solution of (NE) and $\pi(x)$ is the projection of x onto the underlying set C .

In the first stage we remove lines from the set C , to form a reduced problem (over \tilde{C}) as outlined in the theory above. The lineality space of C as defined by (2) is

$$\text{lin } C = \ker \begin{bmatrix} B \\ H \end{bmatrix}$$

We calculate bases for the lineality space and its orthogonal complement by performing a QR factorization (with column pivoting) of $\begin{bmatrix} B^T & H^T \end{bmatrix}$. If $\begin{bmatrix} w & v \end{bmatrix}$ represents these bases, the reduced problem is to solve the normal equation

$$\tilde{A}_{\tilde{C}} y = \tilde{a} \quad (3)$$

where

$$\tilde{C} = \{z \mid \tilde{B}z \geq b, \tilde{H}z = h\}, \quad \tilde{B} = BV, \quad \tilde{H} = HV. \quad (4)$$

Here

$$\tilde{A} = U^T AU, \quad \tilde{a} = V^T (I - AZ) a \quad (5)$$

with

$$Z = W(W^T AW)^{-1} W^T, \quad U = (I - ZA)V \quad (6)$$

and Z satisfies $Z^T AZ = Z^T$. In practice, \tilde{A} and \tilde{a} are calculated using one LU factorization of $W^T AW$. Furthermore, the solution pair $(x, \pi(x))$ of the original normal equation (NE) can be recovered from the solution pair $(y, \pi(y))$ of (3) using the identities

$$\begin{aligned} x_l &= Z(b - AV\pi(y)) \\ x &= x_l + Vy \\ \pi(x) &= x_l + V\pi(y) \end{aligned}$$

Therefore, we can assume that the problem has the form (3), with \tilde{C} given by (4) and that the matrix $\begin{bmatrix} \tilde{B} \\ \tilde{H} \end{bmatrix}$ has full column rank.

In the second stage, we determine an extreme point of the set \tilde{C} , and using this information reduce the problem further by forcing the iterates to lie in the affine space generated by the equality constraints. More precisely, we have the following result:

Lemma 3.1. *Suppose $y_e \in \tilde{C}$ and Y is a basis for the kernel of \tilde{H} . Then \bar{y} solves (3) if and only if $\bar{y} = y_e + Y\bar{x}$ where \bar{x} solves*

$$\bar{A}_{\tilde{C}}x = \bar{a} \tag{7}$$

Here $\bar{A} = Y^T \tilde{A}Y$, $\bar{a} = Y^T(\tilde{a} - \tilde{A}y_e)$ and $\tilde{C} = \{z \mid \tilde{B}Yz \geq b - \tilde{B}y_e\}$. Furthermore, $\tilde{B}Y$ has full column rank if and only if $\begin{bmatrix} \tilde{B} \\ \tilde{H} \end{bmatrix}$ has full column rank.

Thus, to reduce our problem to one over an inequality constrained polyhedral set, it remains to show how we generate the point $y_e \in \tilde{C}$. In fact we show how to generate y_e as an extreme point of \tilde{C} and further, how to project this extreme point into an extreme point of \tilde{C} . The following result is a well known characterization of extreme points of polyhedral sets [9, §3.4].

Lemma 3.2. *Let u be partitioned into free and constrained variables $(u_{\mathcal{F}}, u_{\mathcal{C}})$. u is an extreme point of $\mathcal{D} = \{u = (u_{\mathcal{F}}, u_{\mathcal{C}}) \mid Du = d, u_{\mathcal{C}} \geq 0\}$ if and only if $u \in \mathcal{D}$ and $\{d_i \mid i \in \mathcal{B}\}$ are linearly independent, where $\mathcal{B} := \mathcal{F} \cup \{j \in \mathcal{C} \mid u_j > 0\}$.*

If we adopt the terminology of linear programming, then the variables corresponding to \mathcal{B} are called basic variables; similarly, the columns of D corresponding to \mathcal{B} are called basic columns; extreme points are called basic feasible solutions.

The extreme points of systems of inequalities and equalities are defined in an analogous manner. Note that extreme points of \tilde{C} are (by definition) precisely the extreme points of

$$\begin{bmatrix} \tilde{B} & -I \\ \tilde{H} & 0 \end{bmatrix} \begin{bmatrix} z \\ s \end{bmatrix} = \begin{bmatrix} b \\ h \end{bmatrix}, s \geq 0. \tag{8}$$

The slack variables s are implicitly defined by z , so without ambiguity we will refer to the above extreme point as z . For other systems of inequalities and equations a similar convention will be used. The following lemma outlines our method for constructing the relevant extreme points.

Lemma 3.3. *Suppose $\begin{bmatrix} \tilde{B} \\ \tilde{H} \end{bmatrix}$ has linearly independent columns, Y is a basis of the kernel of \tilde{H} and $\tilde{B} = \tilde{B}Y$. Then y_e is an extreme point of (8) if and only if $y_e = y_* + Yz_*$, for some y_*, z_* where $\tilde{H}y_* = h$ and z_* is an extreme point of*

$$\begin{bmatrix} \tilde{B} & -I \end{bmatrix} \begin{bmatrix} z \\ s \end{bmatrix} = b - \tilde{B}y_*, s \geq 0. \quad (9)$$

In our method we produce an extreme point of (8) as follows. Find orthonormal bases U and Y for $\text{im } \tilde{H}$ and $\text{ker } \tilde{H}$ respectively. This can be carried out by a singular value decomposition of \tilde{H} or by QR factorizations of \tilde{H} and \tilde{H}^T (in fact, Y could be calculated as a by-product of stage 1 of the algorithm). Let $y_* = UU^T h$ and use this value of y_* in (9). If $b \notin \text{im } \tilde{B}$, then find an extreme point of (9) by solving the following auxiliary problem with the revised simplex method:

$$\begin{aligned} & \text{minimize} && z_{aux} \\ & \text{subject to} && \begin{bmatrix} \tilde{B} & b - \tilde{B}y_* \end{bmatrix} \begin{bmatrix} z \\ z_{aux} \end{bmatrix} \geq b - \tilde{B}y_* \\ & && z_{aux} \geq 0. \end{aligned}$$

Note that $z = 0, z_{aux} = 1$ is an initial feasible point for this problem, with basic variables (z, z_{aux}) . In contrast to the usual square basis matrix (with corresponding LU factors), we use a QR factorization of the non square basis matrix. The calculations of dual variables and incoming columns are performed in a least squares sense using the currently available QR factorization. This factorization is updated at each pivot step either by using a rank-one update to the factorization or by adding a column to the factorization (see [6]). In order to invoke Lemma 3.1, we let $y_e = y_* + Yz_*$ be the feasible point needed to define (7).

Note that in the well known method of Lemke, stages one and two are trivial since $C = \mathbb{R}_+^n$ has no lines and a single extreme point at 0. Furthermore, stage one is an exact implementation of the theory outlined in the previous section and stage two corresponds to determining an extreme point and treating the defining equalities of C in an effective computational manner.

It remains to describe stage three of our method. We are able to assume that our problem is given as

$$\bar{A}_{\bar{C}}x = \bar{a} \quad (10)$$

with $\bar{C} = \{z \mid \bar{B}z \geq \bar{b}\}$, where \bar{B} has full column rank and x_e is an extreme point of \bar{C} (easily determined from z_*). We also have available a basis matrix corresponding to this extreme point along with a QR factorization, courtesy of stage two.

The method that we use to solve this problem is precisely a realization of the general scheme for piecewise linear equations developed by [3]. The general method of Eaves (assuming a ray start and regular value v) moves along the curve $F^{-1}(v)$ in the direction d_1 from x_1 and can be described as follows:

Algorithm 1**Initialize :**

Let L_{σ_k} denote the linear map representing F on the cell σ_k . Determine (x_1, σ_1, d_1) satisfying

$$\begin{aligned} L_{\sigma_1} d_1 &= 0, d_1 \text{ points into } \sigma_1 \text{ at } x_1. \\ F(x_1) &= v \end{aligned} \tag{11}$$

$$x_1 \in \sigma_1 \in \mathcal{M}, x_1 \in \text{int} \{x - \theta d_1 \mid \theta \geq 0\} \subset F^{-1}v. \tag{12}$$

Iteration :

Given (x_k, σ_k, d_k) let

$$\theta_k := \sup \{ \theta \mid x_k + \theta d_k \in \sigma_k \} \tag{13}$$

If $\theta_k = +\infty$ then ray termination.

If $x_{k+1} := x_k + \theta_k d_k \in \partial \mathcal{M}$ then boundary termination.

Otherwise determine $(x_{k+1}, \sigma_{k+1}, d_{k+1})$, $d_{k+1} \neq 0$, satisfying

$$\begin{aligned} L_{\sigma_{k+1}} d_{k+1} &= 0, \text{ and } d_{k+1} \text{ points into } \sigma_{k+1} \text{ from } x_{k+1}. \\ \sigma_{k+1} &\in \mathcal{M} \setminus \{\sigma_k\} \text{ with } x_{k+1} \in \sigma_{k+1} \end{aligned} \tag{14}$$

Set $k = k + 1$ and repeat iteration.

How does this relate to the description we gave in the previous section? The manifold we consider is

$$\mathcal{M} = \mathcal{N}_{\bar{C}} \times \mathbb{R}_+$$

and the corresponding cells $\sigma_{\mathcal{A}}$ are given by

$$(F_{\mathcal{A}} + N_{F_{\mathcal{A}}}) \times \mathbb{R}_+$$

where $F_{\mathcal{A}}$ are the faces of \bar{C} .

A face of \bar{C} is described by the set of constraints from the system $\bar{B}z \geq \bar{b}$ which are active. Let \mathcal{A} represent such a set so that

$$F_{\mathcal{A}} = \{z \mid \bar{B}_{\mathcal{A}}z = \bar{b}_{\mathcal{A}}, \bar{B}_{\mathcal{I}}z \geq \bar{b}_{\mathcal{I}}\}$$

where \mathcal{I} is the complement of the set \mathcal{A} . The normal cone to the face (the normal cone to \bar{C} at some point in the relative interior of $F_{\mathcal{A}}$) is given by

$$\{\bar{B}^T u \mid u_{\mathcal{A}} \leq 0, u_{\mathcal{I}} = 0\}$$

It now follows that an algebraic description of $(x, \mu) \in \sigma_{\mathcal{A}}$ is that there exist $(x, z, u_{\mathcal{A}}, s_{\mathcal{I}}, \mu)$ which satisfy

$$\begin{aligned} \bar{B}_{\mathcal{A}}z &= \bar{b}_{\mathcal{A}} \\ \bar{B}_{\mathcal{I}}z - s_{\mathcal{I}} &= \bar{b}_{\mathcal{I}}, s_{\mathcal{I}} \geq 0 \\ x &= z + \bar{B}_{\mathcal{A}}^T u_{\mathcal{A}}, u_{\mathcal{A}} \leq 0 \\ \mu &\geq 0 \end{aligned} \tag{15}$$

In particular, if x_e is the given extreme point, the corresponding face of the set \bar{C} is used to define the initial cell σ_1 . The piecewise linear system we solve is

$$F(x, \mu) := \bar{A}_{\bar{C}}(x) - (\mu e + \bar{a}) = 0$$

where e is a point in the interior of $N_{\bar{C}}(x_e)$. An equivalent description of $N_{\bar{C}}(x_e)$ is given by

$$\{\bar{B}_{\mathcal{A}}^T u \mid u \leq 0\}$$

from which it is clear that the interior of this set is nonempty if and only if $\bar{B}_{\mathcal{A}}$ has full column rank.

Lemma 3.4. *If x_e is an extreme point of $\{z \mid \bar{B}z \geq \bar{b}\}$ with active constraints \mathcal{A} , then $\bar{B}_{\mathcal{A}}$ has full column rank.*

Proof. By definition,

$$G := \begin{bmatrix} \bar{B}_{\mathcal{A}} & 0 \\ \bar{B}_{\mathcal{I}} & -I \end{bmatrix} \tag{16}$$

has linearly independent columns. If $\bar{B}_{\mathcal{A}}$ does not have linearly independent columns, then $\bar{B}_{\mathcal{A}}w = 0$, for some $w \neq 0$, so that

$$G \begin{bmatrix} w \\ \bar{B}_{\mathcal{I}}w \end{bmatrix} = 0$$

with $(w, \bar{B}_{\mathcal{I}}) \neq 0$, a contradiction of (16). \square

This is a simple proof (in this particular instance) of the comment from the previous section that the normal cone has interior at an extreme point. For consistency, we shall let e be any point in this interior $\{\bar{B}_{\mathcal{A}}^T u \mid u \leq 0\}$, and for concreteness we could take

$$e = -\bar{B}_{\mathcal{A}}^T \begin{bmatrix} 1 \\ \vdots \\ 1 \end{bmatrix}.$$

Hence F is specified, $v = 0$ and the cells of $\sigma_{\mathcal{A}}$ are defined. By solving the perturbed system $F(x_\epsilon, \mu_\epsilon) = p(\epsilon)$ (as outlined in §2), we know that $F^{-1}(p(\epsilon))$ is a connected 1-manifold whose boundary is equal to its intersection with the boundary of \mathcal{M} and which is subdivided by the chords formed by its intersections with the cells of \mathcal{M} that it meets. In practice, this means that (under the lexicographical ordering induced by $p(\epsilon)$) we may assume nondegeneracy. Thus, if ties ever occur in the description that follows, we will always choose the the lexicographical minimum from those which achieve the tie.

Note that if $(x, \mu) \in \sigma_{\mathcal{A}}$ as defined in (15) then

$$F(x, \mu) = \bar{A}z + x - z - \mu e - \bar{a}$$

It follows that if $(x, \mu) \in \sigma_{\mathcal{A}} \cap F^{-1}(0)$ (i.e. (x, μ) is in one of the chords mentioned in the previous paragraph), then there exist $(x, z, u_{\mathcal{A}}, s_{\mathcal{I}}, \mu)$ satisfying

$$\begin{aligned} x - z &= -\bar{A}z + \mu e + \bar{a} \\ \bar{B}_{\mathcal{A}}z &= \bar{b}_{\mathcal{A}} \\ \bar{B}_{\mathcal{I}}z - s_{\mathcal{I}} &= \bar{b}_{\mathcal{I}}, s_{\mathcal{I}} \geq 0 \\ x - z &= \bar{B}_{\mathcal{A}}^T u_{\mathcal{A}}, u_{\mathcal{A}} \leq 0 \\ \mu &\geq 0 \end{aligned} \tag{17}$$

Furthermore, these equations determine the chord on the current cell of the manifold, or in the notation used to describe the algorithm of Eaves, the map $L_{\sigma_{\mathcal{A}}}$. The direction is determined from (11) by solving $L_{\sigma_{\mathcal{A}}}d = 0$, which can be calculated by solving

$$\begin{aligned} \Delta x - \Delta z &= -\bar{A}\Delta z + e\Delta\mu \\ \bar{B}_{\mathcal{A}}\Delta z &= 0 \\ \bar{B}_{\mathcal{I}}\Delta z - \Delta s_{\mathcal{I}} &= 0 \\ \Delta x - \Delta z &= \bar{B}_{\mathcal{A}}^T \Delta u_{\mathcal{A}} \end{aligned} \tag{18}$$

At the first iteration, $\bar{B}_{\mathcal{A}}$ has full column rank, so that $\Delta z = 0$, which also implies that $\Delta s_{\mathcal{I}} = 0$. The remaining system of equations is

$$\begin{aligned} \Delta x &= e\Delta\mu \\ \Delta x &= \bar{B}_{\mathcal{A}}^T \Delta u_{\mathcal{A}} \end{aligned}$$

We choose $\Delta\mu = -1$ in order to force the direction to move into σ_1 (as required by (11)), and then it follows that $\Delta x = -e$ for the choice of e outlined above $\Delta u_{\mathcal{A}} = (1, \dots, 1)^T$. The actual choice $x_1 = (w(\mu), \mu)$ given in the previous section ensures that (12) is satisfied.

We can now describe the general iteration and the resultant linear algebra that it entails. We are given a current point $(x, z, u_{\mathcal{A}}, s_{\mathcal{I}}, \mu)$ satisfying (17) for some cell $\sigma_{\mathcal{A}}$ and a direction $(\Delta x, \Delta z, \Delta u_{\mathcal{A}}, \Delta s_{\mathcal{I}}, \Delta\mu)$ satisfying (18). The value of θ_k to satisfy (13) can be calculated by the following ratio test; that is to find the largest θ such that

$$\begin{aligned} u_{\mathcal{A}} + \theta\Delta u_{\mathcal{A}} &\leq 0 \\ s_{\mathcal{I}} + \theta\Delta s_{\mathcal{I}} &\geq 0 \\ \mu + \theta\Delta\mu &\geq 0 \end{aligned} \tag{19}$$

Ray termination occurs if $\Delta u_{\mathcal{A}} \leq 0$, $\Delta s_{\mathcal{I}} \geq 0$ and $\Delta\mu \geq 0$. Obviously, if $\mu + \theta\Delta\mu = 0$, then we have a solution. Otherwise, at least one of the $\{u_i \mid i \in \mathcal{A}\}$ or $\{s_i \mid i \in \mathcal{I}\}$ hits a bound in (19). By the lexicographical ordering we can determine the ‘‘leaving’’ variable from these uniquely. The set \mathcal{A} is updated (corresponding to moving onto a new cell of the manifold) and a new direction is calculated as follows: if u_i , $i \in \mathcal{A}$ is the leaving variable, then $\mathcal{A} := \mathcal{A} \setminus \{i\}$, $\Delta s_i = 1$ and the new direction is found by solving (18); if s_i , $i \in \mathcal{I}$ is the leaving variable, then $\mathcal{A} := \mathcal{A} \cup \{i\}$, $\Delta u_i = -1$ and the new direction is found by solving (18). Note that in both cases, the choice of one component of the direction ensures movement into the new (uniquely specified) cell $\sigma_{\mathcal{A}}$ and forces a unique solution of (18).

The linear algebra needed for an implementation of the method is now clear. The actual steps used to carry out stage 3 are now described. First of all, x is eliminated from (17) to

give

$$\begin{aligned} -\bar{A}z + \mu e + \bar{a} &= \bar{B}_A^T u_A + \bar{B}_I^T u_I \\ \bar{B}_A z - s_A &= \bar{b}_A \\ \bar{B}_I z - s_I &= \bar{b}_I \\ \mu \geq 0, u_A \leq 0, u_I = 0, s_I \geq 0, s_A = 0 \end{aligned}$$

Note that we have added in the variables which are set to zero for completeness. The QR factorization corresponding to the given extreme point is used to eliminate the variables z . In fact, we take as our initial active set \mathcal{A} , the variables corresponding to $Q\hat{R}$, where \hat{R} is the invertible submatrix of R . Thus

$$z = \bar{B}_A^{-1}(s_A + \bar{b}_A)$$

and substituting this into the above gives

$$\begin{aligned} -\bar{A}\bar{B}_A^{-1}(s_A + \bar{b}_A) + \mu e + \bar{a} &= \bar{B}_A^T u_A + \bar{B}_I^T u_I \\ \bar{B}_I \bar{B}_A^{-1}(s_A + \bar{b}_A) - s_I &= \bar{b}_I \\ \mu \geq 0, u_A \leq 0, u_I = 0, s_I \geq 0, s_A = 0 \end{aligned}$$

Essentially we treat this system as in the method of Lemke. An initial basis is given by (u_A, s_I) and complementary pivots can then be executed (using the variables u and s as the complementary pair). Any basis updating technique or anti-cycling rule can be incorporated from the literature on linear programming and complementarity. In fact we have an initial QR factorization of the basis available from the given factorization if needed.

We showed in the previous section that if A_C was coherently oriented then following the above path gives a monotonic decrease in μ . However, the proof of the finite termination of the method (possibly ray termination) goes through without this assumption, and in the following section we will look at other conditions which guarantee that the method terminates either with a solution or a proof that no solution exists. The coherent orientation results are direct analogues of the P -matrix results for the linear complementarity problem – the results we shall give now generalize the notions of copositive plus and L -matrices.

4. EXISTENCE RESULTS

The following definitions are generalizations of those found in the literature.

Definition 4.1. Let K be a given closed convex cone. A matrix A is said to be copositive with respect to the cone K if

$$\langle x, Ax \rangle \geq 0, \forall x \in K$$

A matrix A is said to be copositive-plus with respect to the cone K if it is copositive with respect to K and

$$\langle x, Ax \rangle = 0, x \in K \implies (A + A^T)x = 0$$

Definition 4.2. Let K be a given closed convex cone. A matrix A is said to be L -matrix with respect to K if both

a) For every $q \in \text{ri}(K^D)$, the solution set of the generalized complementarity problem

$$z \in K, \quad Az + q \in K^D, \quad z^T(Az + q) = 0 \tag{20}$$

is contained in $\text{lin } K$.

b) For any $z \neq 0$ such that

$$z \in K, \quad Az \in K^D, \quad z^T Az = 0$$

there exists $z' \neq 0$, such that z' is contained in every face of K containing z and $-A^T z'$ is contained in every face of K^D containing Az .

To see how do these definitions relate to the standard ones given in the literature on linear complementarity problems (e.g. [10] and [2]), consider the case that $C = \mathbb{R}_+^n$ and $K = \text{rec } C = \mathbb{R}_+^n$. Condition a) says that $\text{LCP}(q, A)$ has a unique solution 0 for all $q > 0$. Condition b) states that, if $z \neq 0$ is a solution of $\text{LCP}(0, A)$, then there exists $z' \neq 0$ such that z' is contained in every face of \mathbb{R}_+^n containing z and $-A^T z'$ is contained in every face of \mathbb{R}_+^n containing Az . In particular, $z' \in \{x \in \mathbb{R}^n \mid x_i = 0\}$, for all $i \in \{i \mid z_i = 0\}$. Hence $z'_i = 0$ for each i such that $z_i = 0$. That is, $\text{supp } z' \subset \text{supp } z$. In another words, there exists a diagonal matrix $D \geq 0$ such that $z' = Dz$. Similarly, there exists a diagonal matrix $E \geq 0$ such that $-A^T z' = EAz$. Hence

$$(EA + A^T D)z = 0$$

where $D, E \geq 0$ and $Dz \neq 0$. Thus the notion of L -matrix defined here is a natural extension of that presented in [10]. The following lemma shows that the class L -matrices contains the class copositive-plus matrices.

Lemma 4.3. *If a matrix A is copositive-plus with respect to a closed convex cone K , then it is an L -matrix with respect to K .*

Proof. Suppose that $q \in \text{ri}(K^D)$ and $z \in K \setminus \text{lin } K$, then $\pi_{(\text{lin } K)^\perp}(z) \neq 0$. Furthermore, there exists an $\epsilon > 0$, such that $q - \epsilon \pi_{(\text{lin } K)^\perp}(z) \in K^D$, since $\text{aff}(K^D) = (\text{lin } K)^\perp$ (cf. [12, Theorem 14.6]). It follows that

$$0 \leq \langle z, q - \epsilon \pi_{(\text{lin } K)^\perp}(z) \rangle = \langle z, q \rangle - \epsilon \langle z, \pi_{(\text{lin } K)^\perp}(z) \rangle = \langle z, q \rangle - \epsilon \left\| \pi_{(\text{lin } K)^\perp}(z) \right\|_2^2$$

That is $\langle z, q \rangle \geq \epsilon \left\| \pi_{(\text{lin } K)^\perp}(z) \right\|_2^2 > 0$. Also $z^T Az \geq 0$ since A is copositive with respect to K . Thus $z^T(Az + q) = z^T Az + z^T q \geq z^T q > 0$. This shows that the set $K \setminus \text{lin } K$ does not contain any solution of (20). Therefore the solution set of the problem (20) is contained in $\text{lin } K$.

To complete the proof, note that for any $z \in K$, such that $Az \in K^D$ and $z^T Az = 0$, we have $Az + A^T z = 0$, or $-A^T z = Az$, since A is copositive-plus. So the condition b) of Definition 4.2 is satisfied with $z' = z$. \square

We now come to the main result of this section.

Theorem 4.4. *Suppose C is a polyhedral convex set and A is an L -matrix with respect to $\text{rec } C$ which is invertible on the lineality space of C . Then exactly one of the following occurs:*

- *The method given above solves (AVI)*
- *the following system has no solution*

$$Ax - a \in (\text{rec } C)^D, \quad x \in C \tag{21}$$

Proof. Suppose that $C = \{z \mid Bz \geq b, Hz = h\}$. We may assume that (AVI) is in the form (10) due to Lemma A.4 and Lemma A.5. The pivotal method fails to solve (AVI) only if, at some iterate x_k , it reaches an unbounded direction d_{k+1} in σ_{k+1} . We know that x_k satisfies (17), and the direction d_{k+1} which satisfies $L_{\sigma_{k+1}} d_{k+1} = 0$ can be found by solving (18). Suppose $(\Delta x, \Delta z, \Delta u_{\mathcal{A}}, \Delta s_{\mathcal{I}}, \Delta \mu)$ is a solution of (18), then

$$\Delta u_{\mathcal{A}} \leq 0, \quad \Delta s_{\mathcal{I}} \geq 0, \quad \Delta \mu \geq 0 \quad (22)$$

provided that $x_k + \theta d_{k+1}$ is an unbounded ray. By reference to (18), we have

$$\begin{aligned} \bar{B}_{\mathcal{A}}^T \Delta u_{\mathcal{A}} + \bar{A} \Delta z &= e \Delta \mu \\ \bar{B}_{\mathcal{A}} \Delta z &= 0 \\ \bar{B}_{\mathcal{I}} \Delta z &= \Delta s_{\mathcal{I}} \geq 0 \end{aligned} \quad (23)$$

That is, Δz satisfies

$$\begin{aligned} \Delta z &\in \text{rec } \bar{C} \\ \bar{A} \Delta z - e \Delta \mu &= \bar{B}_{\mathcal{A}}^T (-\Delta u_{\mathcal{A}}) \in (\text{rec } \bar{C})^D \\ \Delta z^T (\bar{A} \Delta z - e \Delta \mu) &= \Delta z^T \bar{B}_{\mathcal{A}}^T (-\Delta u_{\mathcal{A}}) = -(\bar{B}_{\mathcal{A}} \Delta z)^T \Delta u_{\mathcal{A}} = 0 \end{aligned}$$

If $\Delta \mu > 0$, then $e \Delta \mu \in \text{int } N_{\bar{C}}(x_e)$, hence $-e \Delta \mu \in \text{int}(\text{rec } \bar{C})^D$. The above system has a unique solution $\Delta z = 0$ by the fact that \bar{A} is an L -matrix with respect to $\text{rec } \bar{C}$ and $\text{lin } \bar{C} = \{0\}$. Therefore the terminating ray is the starting ray, a contradiction. Thus $\Delta \mu = 0$. It follows that $\Delta z \in \text{rec } \bar{C}$, $\bar{A} \Delta z \in (\text{rec } \bar{C})^D$, and $z^T \bar{A} z = 0$, therefore there exist $\tilde{z} \neq 0$, such that \tilde{z} is contained in every face of $\text{rec } \bar{C}$ containing Δz , and that $-\bar{A}^T \tilde{z}$ is contained in every face of $(\text{rec } \bar{C})^D$ containing $\bar{A} \Delta z$. We observe that, since $x_k \in \sigma_k \cap \sigma_{k+1} \cap F^{-1}(0)$, there exist z_k, u_k, s_k , and μ_k such that (17) is satisfied. It is easy to verify that Δz is in the face

$$G_1 = \left\{ z \in \text{rec } \bar{C} \mid z^T (\bar{B}^T u_k) = 0 \right\}$$

of $\text{rec } \bar{C}$, and $\bar{A} \Delta z$ is in the face

$$G_2 = \left\{ z \in (\text{rec } \bar{C})^D \mid z = \bar{B}^T u, u = (u_{\mathcal{A}}, 0) \geq 0 \right\}$$

of $(\text{rec } \bar{C})^D$, and thus

$$-\bar{A}^T \tilde{z} = \bar{B}^T \tilde{u} \in G_2, \quad \text{for some } \tilde{u} = (\tilde{u}_{\mathcal{A}}, 0) \geq 0 \quad (24)$$

Consequently, by (17) we have

$$\bar{a} = x_k - z_k + \bar{A} z_k - e \mu$$

$$\tilde{u}^T (\bar{B} z_k - \bar{b}) = (\tilde{u}_{\mathcal{A}}^T, 0) \begin{pmatrix} 0 \\ s_{\mathcal{I}} \end{pmatrix} = 0$$

and

$$\tilde{z}^T (x_k - z_k) = \tilde{z}^T \bar{B}^T u_k = 0$$

since $\tilde{z} \in G_1$. Therefore

$$\begin{aligned}\tilde{u}^T \bar{b} + \tilde{z}^T \bar{a} &= \tilde{u}^T (\bar{b} - \bar{B}z_k) + \tilde{u}^T \bar{B}z_k + \tilde{z}^T (x_k - z_k + \bar{A}z_k - e\mu) \\ &= (\bar{B}^T \tilde{u} + \bar{A}^T \tilde{z})^T z_k - \mu e^T \tilde{z} \\ &= -\mu e^T \tilde{z} > 0\end{aligned}$$

in which the last inequality is due to $\tilde{z} \in \text{rec } \bar{C}$ and $e \in \text{int } N_{\bar{C}}(x_e) \subset -\text{int}(\text{rec } \bar{C})^D$. We now claim that the the system

$$\bar{A}x - \bar{a} \in (\text{rec } \bar{C})^D, \quad x \in \bar{C} \quad (25)$$

has no solution. To see this, let $x \in \bar{C}$, then

$$\tilde{u}^T \bar{B}x + \tilde{z}^T \bar{A}x = 0$$

as a result of (24). Subtract from this the inequality

$$\tilde{u}^T \bar{b} + \tilde{z}^T \bar{a} > 0$$

which we have just proven, then

$$\tilde{u}^T (\bar{B}x - \bar{b}) + \tilde{z}^T (\bar{A}x - \bar{a}) < 0$$

But it is obvious that $\tilde{u}^T (\bar{B}x - \bar{b}) \geq 0$, hence

$$\tilde{z}^T (\bar{A}x - \bar{a}) < 0$$

But $\tilde{z} \in \text{rec } \bar{C}$. Thus $\bar{A}x - \bar{a} \notin (\text{rec } \bar{C})^D$.

The proof is complete by noting that (25) has a solution if and only if (21) has a solution. \square

As a special case of this theorem, we have the following result for copositive-plus matrices.

Corollary 4.5. *Suppose C is a polyhedral convex set, A is copositive-plus with respect to $\text{rec } C$ and invertible on the lineality space of C . Then exactly one of the following occurs:*

- *The method given above solves (AVI)*
- *the following system has no solution*

$$Ax - a \in (\text{rec } C)^D, \quad x \in C \quad (26)$$

Proof. Obvious, in view of Lemma 4.3. \square

APPENDIX A. INVARIANCE PROPERTIES OF L -MATRICES

In this appendix we show that the property of L -matrix with respect to a polyhedral convex cone is invariant under the two reductions presented in §3. We begin with the following technical lemmas.

Lemma A.1. *Let C , \tilde{C} , and \bar{C} be as in (AVI), (3) and (10); V and Y be as in (6) and Lemma 3.1. Then*

$$\text{rec } C = V(\text{rec } \tilde{C}) \quad (27)$$

$$\text{rec } \tilde{C} = Y(\text{rec } \bar{C}) \quad (28)$$

and

$$V^T((\text{rec } C)^D) = (\text{rec } \tilde{C})^D \quad (29)$$

$$Y^T((\text{rec } \tilde{C})^D) = (\text{rec } \bar{C})^D \quad (30)$$

Furthermore

$$V^T(\text{ri}((\text{rec } C)^D)) = \text{ri}(\text{rec } \tilde{C})^D \quad (31)$$

$$Y^T(\text{ri}(\text{rec } \tilde{C})^D) = \text{ri}(\text{rec } \bar{C})^D \quad (32)$$

Proof. (27) and (28) are obvious from definition.

Based on these two equations and [12, Corollary 16.3.2], we have

$$\begin{aligned} (\text{rec } C)^D &= -(\text{rec } C)^\circ = -(V \text{rec } \tilde{C})^\circ \\ &= -(V^T)^{-1}(\text{rec } \tilde{C})^\circ = (V^T)^{-1}(\text{rec } \tilde{C})^D \end{aligned}$$

where $K^\circ = -K^D$ is the polar cone of K and $(V^T)^{-1}$ is the inverse image of the linear map V^T (also see [12]). Similarly

$$(\text{rec } \tilde{C})^D = (Y \text{rec } \bar{C})^D = (Y^T)^{-1}(\text{rec } \bar{C})^D$$

So we have proven (29) and (30).

(31) and (32) can be obtained from (29) and (30) by applying [12, Theorem 6.6]. \square

Lemma A.2. For $z \in \text{rec } C$, $\tilde{z} \in \text{rec } \tilde{C}$, and $\bar{z} \in \text{rec } \bar{C}$, define

$$\begin{aligned} D(z) &:= \{d \in (\text{rec } C)^D \mid \langle d, z \rangle = 0\} \\ \tilde{D}(\tilde{z}) &:= \{\tilde{d} \in (\text{rec } \tilde{C})^D \mid \langle \tilde{d}, \tilde{z} \rangle = 0\} \\ \bar{D}(\bar{z}) &:= \{\bar{d} \in (\text{rec } \bar{C})^D \mid \langle \bar{d}, \bar{z} \rangle = 0\} \end{aligned}$$

Then

$$\tilde{D}(\tilde{z}) = V^T D(V\tilde{z}) \quad (33)$$

$$\bar{D}(\bar{z}) = Y^T \tilde{D}(Y\bar{z}) \quad (34)$$

where V and Y are as in (6) and Lemma 3.1.

Proof.

$$\begin{aligned} \tilde{D}(\tilde{z}) &= \{\tilde{d} \in (\text{rec } \tilde{C})^D \mid \langle \tilde{d}, \tilde{z} \rangle = 0\} = \{\tilde{d} \in V^T(\text{rec } C)^D \mid \langle \tilde{d}, \tilde{z} \rangle = 0\} \\ &= V^T \{d \in (\text{rec } C)^D \mid \langle d^T, V\tilde{z} \rangle = 0\} = V^T D(V\tilde{z}) \end{aligned}$$

The other equation can be proven similarly. \square

Actually, for $z \in \text{rec } C$, $D(z)$ is the set of vectors defining faces of $\text{rec } C$ containing z , a vector z' is in every face of $\text{rec } C$ containing z if and only if $\langle d, z' \rangle = 0$ for all $d \in D(z)$. Similar observation can also be made for the set \tilde{C} and \bar{C} .

Lemma A.3. For $w \in (\text{rec } C)^D$, $\tilde{w} \in (\text{rec } \tilde{C})^D$, and $\bar{w} \in (\text{rec } \bar{C})^D$, define

$$\begin{aligned} R(w) &:= \{r \in \text{rec } C \mid \langle r, w \rangle = 0\} \\ \tilde{R}(\tilde{w}) &:= \{\tilde{r} \in \text{rec } \tilde{C} \mid \langle \tilde{r}, \tilde{w} \rangle = 0\} \\ \bar{R}(\bar{w}) &:= \{\bar{r} \in \text{rec } \bar{C} \mid \langle \bar{r}, \bar{w} \rangle = 0\} \end{aligned}$$

Then

$$V\tilde{R}(V^T w) = R(w) \quad (35)$$

$$Y\bar{R}(Y^T \tilde{w}) = \tilde{R}(\tilde{w}) \quad (36)$$

where V and Y are as in (6) and Lemma 3.1.

Proof.

$$\begin{aligned} R(w) &= \{r \in \text{rec } C \mid \langle r, w \rangle = 0\} = \{r \in V(\text{rec } \tilde{C}) \mid \langle r, w \rangle = 0\} \\ &= V\{\tilde{r} \in \text{rec } \tilde{C} \mid \langle \tilde{r}, V^T w \rangle = 0\} = V\tilde{R}(V^T w) \end{aligned}$$

The other equation can be proven similarly. \square

Similar to the case of Lemma A.2, for $w \in (\text{rec } C)^D$, $R(w)$ is the set of vectors defining faces of $(\text{rec } C)^D$ containing w , a vector w' is in every face of $(\text{rec } C)^D$ containing w if and only if $\langle r, w' \rangle = 0$ for all $r \in R(w)$. The situation is similar for the set \tilde{C} and \bar{C} .

Now, we come to the invariance of the L -matrix property.

Lemma A.4. Given the problems (3) and (10). Suppose \tilde{A} is an L -matrix with respect to $\text{rec } \tilde{C}$, then \bar{A} is an L -matrix with respect to $\text{rec } \bar{C}$.

Proof. For $\bar{z} \in \text{rec } \bar{C}$, $Y\bar{z} \in \text{rec } \tilde{C}$. For any $\bar{q} \in \text{ri}(\text{rec } \bar{C})^D$, there exists $\tilde{q} \in \text{ri}(\text{rec } \tilde{C})^D$ such that $\bar{q} = Y^T \tilde{q}$ due to (32). If $\bar{A}\bar{z} + \bar{q} \in (\text{rec } \bar{C})^D$ then

$$Y^T \tilde{A}Y\bar{z} + Y^T \tilde{q} \in (\text{rec } \tilde{C})^D$$

by definition of \bar{A} . Hence

$$\langle \tilde{A}Y\bar{z} + \tilde{q}, Y\bar{z} \rangle = \langle Y^T \tilde{A}Y\bar{z} + Y^T \tilde{q}, \bar{z} \rangle \geq 0, \quad \forall \bar{z} \in \text{rec } \bar{C}$$

It follows from (28) that

$$\langle \tilde{A}Y\bar{z} + \tilde{q}, \bar{z} \rangle \geq 0, \quad \forall \bar{z} \in \text{rec } \bar{C}$$

Thus

$$\tilde{A}Y\bar{z} + \tilde{q} \in (\text{rec } \tilde{C})^D$$

Therefore \bar{z} satisfies

$$\bar{z} \in \text{rec } \bar{C}, \quad \bar{A}\bar{z} + \bar{q} \in (\text{rec } \bar{C})^D, \quad \text{and} \quad \bar{z}^T(\bar{A}\bar{z} + \bar{q}) = 0 \quad (37)$$

with $\bar{q} \in \text{ri}(\text{rec } \bar{C})^D$, implies $Y\bar{z}$ satisfies

$$Y\bar{z} \in \text{rec } \tilde{C}, \quad \tilde{A}Y\bar{z} + \tilde{q} \in (\text{rec } \tilde{C})^D, \quad \text{and} \quad (Y\bar{z})^T[\tilde{A}(Y\bar{z}) + \tilde{q}] = 0 \quad (38)$$

with $\tilde{q} \in \text{ri}(\text{rec } \tilde{C})^D$. Thus, the solution $Y\bar{z}$ of (38) is contained in $\text{lin } \tilde{C} = \{0\}$, which implies that $\bar{z} = 0$. Thus the solution set of (37) is $\{0\} \subset \text{lin } \bar{C}$.

For any $0 \neq \bar{z} \in \text{rec } \bar{C}$ such that

$$\bar{A}\bar{z} \in (\text{rec } \bar{C})^D \quad \text{and} \quad \bar{z}^T \bar{A}\bar{z} = 0$$

we have, $0 \neq Y\bar{z} \in \text{rec } \tilde{C}$, and

$$\tilde{A}Y\bar{z} \in (\text{rec } \tilde{C})^D \quad \text{and} \quad (Y\bar{z})^T \tilde{A}(Y\bar{z}) = 0$$

So, there exists $0 \neq \tilde{z} \in \text{rec } \tilde{C}$ such that \tilde{z} is contained in every face of $\text{rec } \tilde{C}$ containing $Y\bar{z}$, and $-\tilde{A}^T \tilde{z}$ is contained in every face of $(\text{rec } \tilde{C})^D$ containing $\tilde{A}Y\bar{z}$. That is

$$\begin{aligned} \langle \tilde{d}, \tilde{z} \rangle &= 0 \quad \forall \tilde{d} \in \tilde{D}(Y\bar{z}) \\ \langle \tilde{r}, -\tilde{A}^T \tilde{z} \rangle &= 0 \quad \forall \tilde{r} \in \tilde{R}(\tilde{A}Y\bar{z}) \end{aligned}$$

Consequently, there exists $0 \neq \bar{z}' \in \text{rec } \bar{C}$ such that $\tilde{z} = Y\bar{z}'$. For any $\bar{d} \in \bar{D}(\bar{z})$, $\bar{d} = Y^T \tilde{d}$ for some $\tilde{d} \in \tilde{D}(Y\bar{z})$. Hence

$$\langle \bar{d}, \bar{z}' \rangle = \langle Y^T \tilde{d}, \bar{z}' \rangle = \langle \tilde{d}, Y\bar{z}' \rangle = 0$$

So, \bar{z}' is contained every face of $\text{rec } \bar{C}$ containing \bar{z} . Moreover, for any $\bar{r} \in \bar{R}(\bar{A}\bar{z})$

$$\langle \bar{r}, -\bar{A}^T \bar{z}' \rangle = \langle Y\bar{r}, -\tilde{A}^T Y\bar{z}' \rangle = \langle Y\bar{r}, -\tilde{A}^T \tilde{z} \rangle = 0$$

since $Y\bar{z} \in \tilde{R}(\tilde{A}Y\bar{z})$. We see that $-\bar{A}^T \bar{z}'$ is contained in every face of $(\text{rec } \bar{C})^D$ containing $\bar{A}\bar{z}$. Thus \bar{A} is an L -matrix with respect to \bar{C} . \square

Lemma A.5. *Given the problems (NE) and (3). Suppose A is an L -matrix with respect to $\text{rec } C$, then \tilde{A} is an L -matrix with respect to $\text{rec } \tilde{C}$.*

Proof. For any $\tilde{z} \in \text{rec } \tilde{C}$, $V\tilde{z} \in \text{rec } C$ and

$$U\tilde{z} = (V - W(W^T A W)^{-1} W^T A V)\tilde{z} = V\tilde{z} - W(W^T A W)^{-1} W^T A V\tilde{z} \in \text{rec } C$$

since $W(W^T A W)^{-1} W^T A V\tilde{z} \in \text{lin } C$. For any $\tilde{q} \in \text{ri}(\text{rec } \tilde{C})^D$, there exists $q \in \text{ri}(\text{rec } C)^D$ such that $\tilde{q} = V^T q$. If $\tilde{A}\tilde{z} + \tilde{q} \in (\text{rec } \tilde{C})^D$ then

$$U^T A U \tilde{z} + V^T q \in (\text{rec } \tilde{C})^D, \quad q \in (\text{rec } C)^D$$

by definition of \tilde{A} . But

$$U^T A U = V^T A U - V^T A^T W (W^T A W)^{-T} W^T A U = V^T A U$$

since $W^T A U = 0$, as can be directly verified. Thus

$$V^T (A U \tilde{z} + q) = V^T A U \tilde{z} + V^T q \in (\text{rec } \tilde{C})^D, \quad q \in (\text{rec } C)^D$$

which implies

$$\langle A U \tilde{z} + q, V \tilde{z} \rangle = \langle V^T (A U \tilde{z} + q), \tilde{z} \rangle \geq 0, \quad \forall \tilde{z} \in \text{rec } \tilde{C}$$

It follows from (27) that

$$\langle A U \tilde{z} + q, z \rangle \geq 0, \quad \forall z \in \text{rec } C$$

Thus

$$AU\tilde{z} + q \in (\text{rec } C)^D$$

Also

$$(U\tilde{z})^T[A(U\tilde{z}) + q] = \tilde{z}^T \tilde{A}\tilde{z} = 0$$

Therefore \tilde{z} satisfies

$$\tilde{z} \in \text{rec } \tilde{C}, \quad \tilde{A}\tilde{z} + \tilde{q} \in (\text{rec } \tilde{C})^D, \quad \text{and} \quad \tilde{z}^T(\tilde{A}\tilde{z} + \tilde{q}) = 0 \quad (39)$$

with $\tilde{q} \in \text{ri}(\text{rec } \tilde{C})^D$ implies $U\tilde{z}$ satisfies

$$U\tilde{z} \in \text{rec } C, \quad AU\tilde{z} + q \in (\text{rec } C)^D, \quad \text{and} \quad (U\tilde{z})^T[A(U\tilde{z}) + q] = 0 \quad (40)$$

with $q \in \text{ri}(\text{rec } C)^D$. Hence the solution $U\tilde{z} \in \text{lin rec } C = \text{lin } C$. But then

$$V\tilde{z} \in W(W^T A W)^{-1} A^T V\tilde{z} + \text{lin } C \subset \text{lin } C$$

which, by the definition of V , implies $\tilde{z} = 0$. This shows that the solution set of (39) is contained in $\text{lin } \tilde{C} = \{0\}$.

For any $0 \neq \tilde{z} \in \text{rec } \tilde{C}$ such that

$$\tilde{A}\tilde{z} \in (\text{rec } \tilde{C})^D \quad \text{and} \quad \tilde{z}^T \tilde{A}\tilde{z} = 0$$

we have $0 \neq U\tilde{z} \in \text{rec } C$, and

$$V^T A U\tilde{z} = U^T A U\tilde{z} = \tilde{A}\tilde{z} \in (\text{rec } \tilde{C})^D$$

which implies $A(U\tilde{z}) \in (\text{rec } C)^D$. We also have

$$(U\tilde{z})^T A(U\tilde{z}) = \tilde{z}^T \tilde{A}\tilde{z} = 0$$

So, there exists $0 \neq z' \in \text{rec } C$ such that z' is contained in every face of $\text{rec } C$ containing $U\tilde{z}$, and that $-A^T z'$ is contained in every face of $(\text{rec } C)^D$ containing $A(U\tilde{z})$. That is

$$\begin{aligned} \langle d, z' \rangle &= 0 \quad \forall d \in D(U\tilde{z}) \\ \langle r, -A^T z' \rangle &= 0 \quad \forall r \in R(AU\tilde{z}) \end{aligned}$$

Consequently, there exists $0 \neq \tilde{z}' \in \text{rec } \tilde{C}$, such that $z' = V\tilde{z}'$, and for any $\tilde{d} \in \tilde{D}(\tilde{z})$, we have $\tilde{d} = V^T d$, for some $d \in D(V\tilde{z})$, but since $d \in (\text{rec } C)^D$, $W^T d = 0$, therefore $\langle d, V\tilde{z} \rangle = \langle d, U\tilde{z} \rangle$, so $d \in D(V\tilde{z})$ implies $d \in D(U\tilde{z})$, hence

$$\langle \tilde{d}, \tilde{z}' \rangle = \langle V^T d, \tilde{z}' \rangle = \langle d, V\tilde{z}' \rangle = \langle d, z' \rangle = 0$$

So, \tilde{z}' is contained in every face of $\text{rec } \tilde{C}$ containing \tilde{z} . For any $\tilde{r} \in \tilde{R}(\tilde{A}\tilde{z})$

$$\begin{aligned} \langle \tilde{r}, -\tilde{A}^T \tilde{z}' \rangle &= \langle \tilde{r}, -U^T A^T U \tilde{z}' \rangle = \langle \tilde{r}, -U^T A^T V \tilde{z}' \rangle = \langle \tilde{r}, -U^T A^T z' \rangle \\ &= \langle \tilde{r}, -V^T A^T z' \rangle = \langle V\tilde{r}, -A^T z' \rangle = \langle r, -A^T z' \rangle = 0 \end{aligned}$$

since $r = V\tilde{r} \in R(AU\tilde{z})$ as a result of (36). This proved that $-\tilde{A}^T \tilde{z}'$ is contained in every face of $(\text{rec } \tilde{C})^D$ containing $\tilde{A}\tilde{z}$. \square

Acknowledgement. We are grateful to Prof. Stephen Robinson for several enlightening discussion on the material contained in this paper and for his insights into the practicality of the normal equation formulation of the affine variational inequality problem.
